the current thru the generator causes a torque opposing the shaft rotation. This is how generators don't magically create power. The input power is torque times rotation speed. The output power is volts times amps. As the amps go up, the output power goes up. However, this causes the torque on the shaft to go up, so the input power goes up too.

An adaptive control strategy based on the radial basis function NN that enjoys a simple algorithm, strong ability of learning, and fast learning rate is used to adjust virtual inertia adaptively and has good performance in damping of oscillation. The virtual synchronous generator (VSG) based on the energy storage system is proposed to compensate the loss of inertia and ...

Figure (PageIndex{2}): A generator with a single rectangular coil rotated at constant angular velocity in a uniform magnetic field produces an emf that varies sinusoidally in time. Note the generator is similar to a motor, except the shaft is rotated to produce a current rather than the other way around.

( $I_{\text{fault-actual}}$ ) is the fault current in kA. ( $S_{\{r\}}$ ) is the generator power rating in kVA. ( $V_{\{r\}}$ ) is the generator voltage rating in V. ( $Z_{\{\%\}}$ ) is the generator impedance in base percentage. How to calculate the fault current for a generator with the per-unit system? Step 1: Calculate the per unit fault current:
